#### **Table of Contents**

- 1. AJAX
- 2. Asynchronous Programming
- 3. Promises Deep Dive
- 4. Async / Await

#### Have a Question?

# sli.do

# #js-advanced

**AJAX** 

Asynchronous JavaScript and XML

#### What is AJAX?

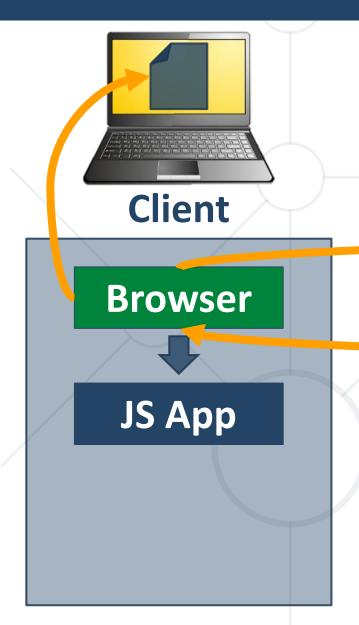

- Background loading of dynamic content/data
- Load data from the Web server and render it
- Some examples of AJAX usage:
  - Partial page rendering
    - Load HTML fragment + show it in a <div>
  - JSON service
    - Loads JSON object and displays it

#### **AJAX: Workflow**

HTTP request (initial page load)

HTTP response (HTML page)

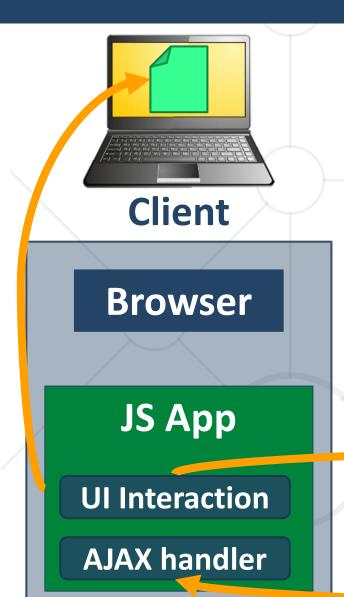

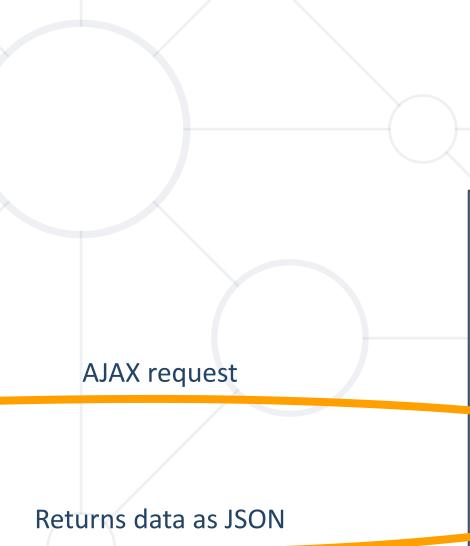

Static

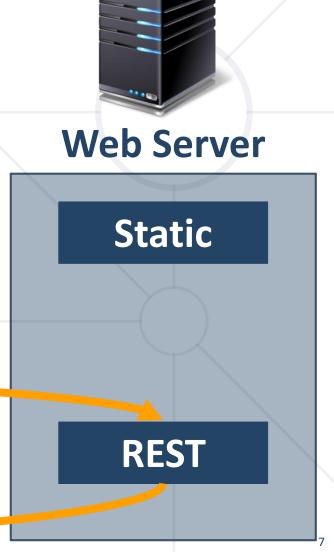

REST

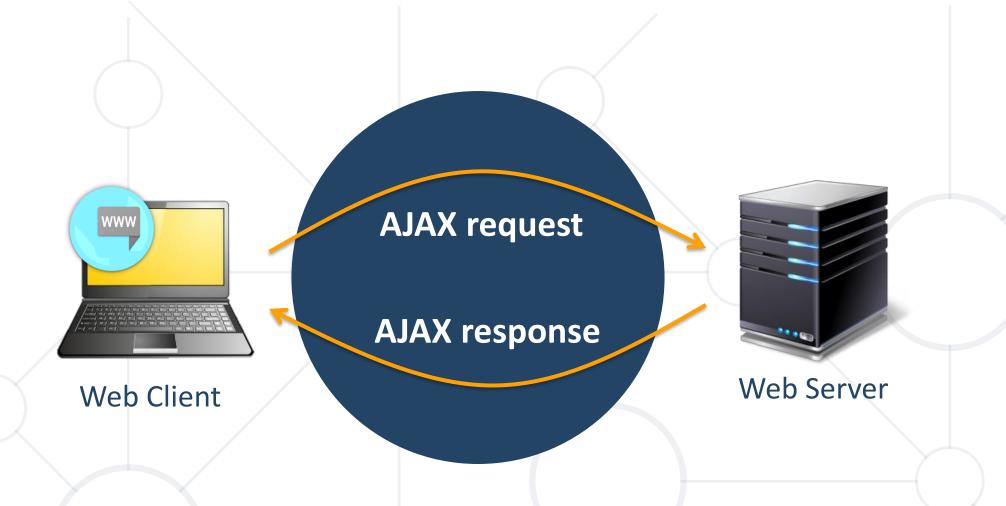

#### **AJAX: Workflow**

# Using the XMLHttpRequest Object

#### XMLHttpRequest – Standard API for AJAX

```
<button id = "load">Load Repos</button>
<div id="res"></div>
```

```
let button = document.querySelector("#load");
button.addEventListener('click', function loadRepos() {
  let url = 'https://api.github.com/users/testnakov/repos';
  const httpRequest = new XMLHttpRequest();
  httpRequest.addEventListener('readystatechange', function () {
      if (httpRequest.readyState == 4 && httpRequest.status == 200) {
         document.getElementById("res").textContent = httpRequest.responseText;
   });
  httpRequest.open("GET", url);
  httpRequest.send();
});
```

# Synchronous vs Asynchronous

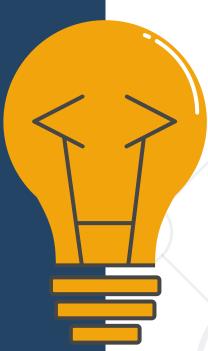

**Asynchronous Programming** 

#### **Asynchronous Programming in JS**

- In current versions of JS there are:
  - Callbacks
  - Promises
  - Async Functions
- Not the same thing as concurrent or multi-threaded
- JS code is generally single-threaded

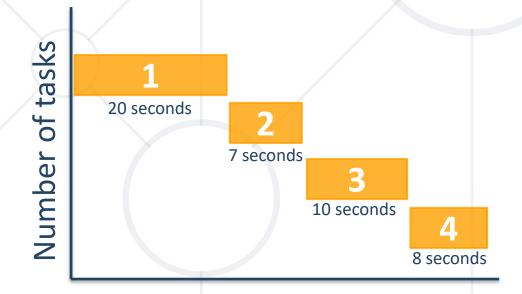

#### **Asynchronous Programming**

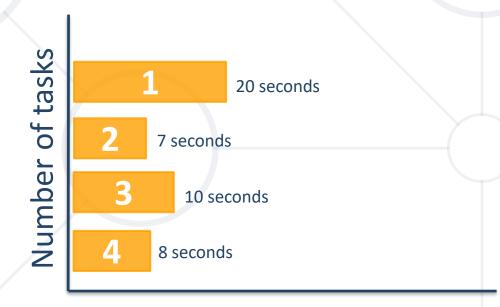

Runs several tasks (pieces of code) in parallel, at the same time

#### Synchronous

#### Asynchronous

#### **Asynchronous Programming – Example**

The following commands will be executed as follows:

```
setTimeout(
console.l
}, 2000);
console.log
```

```
console.log("Hello.");
setTimeout(function() {
  console.log("Goodbye!");
}, 2000);
console.log("Hello again!");
// Goodbye!
// Goodbye!
```

#### **Callbacks**

- Function passed into another function as an argument
- Then invoked inside the outer function to complete some kind of routine or action

```
function running() {
    return "Running";
}
function category(run, type) {
    console.log(run() + " " + type);
}
category(running, "sprint"); //Running sprint
```

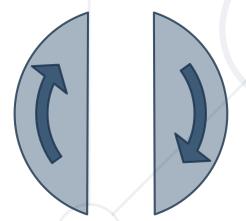

Code executing on the main thread

Event loop is paused during execution

**Event Loop** 

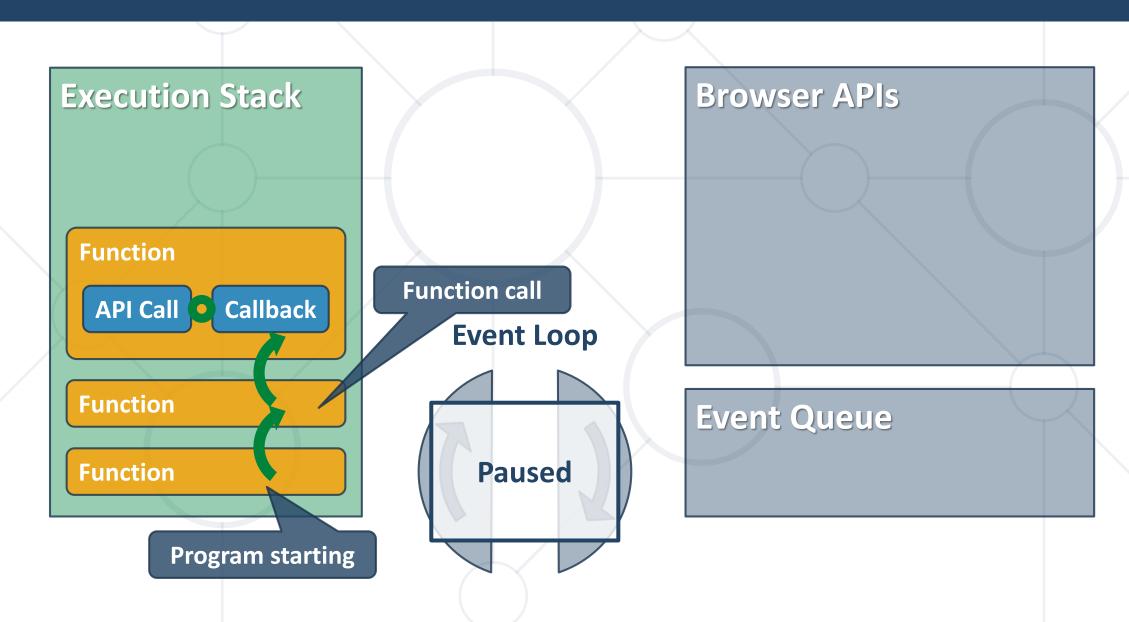

**Browser APIs** 

APIs operate asynchronously

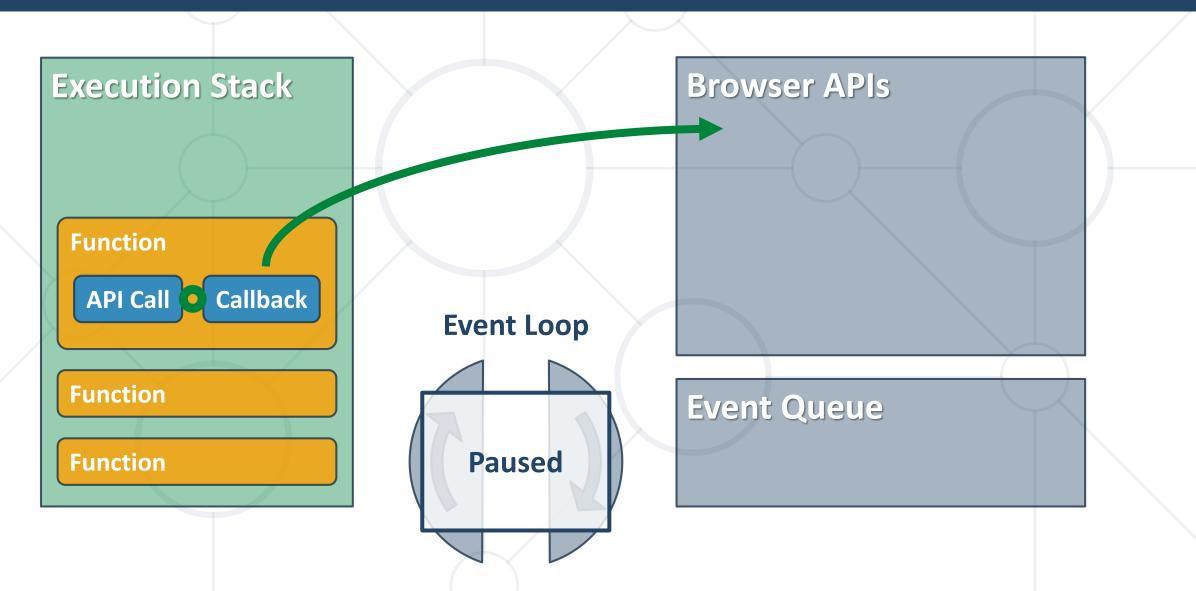

**Event Queue** 

Callbacks wait in the queue

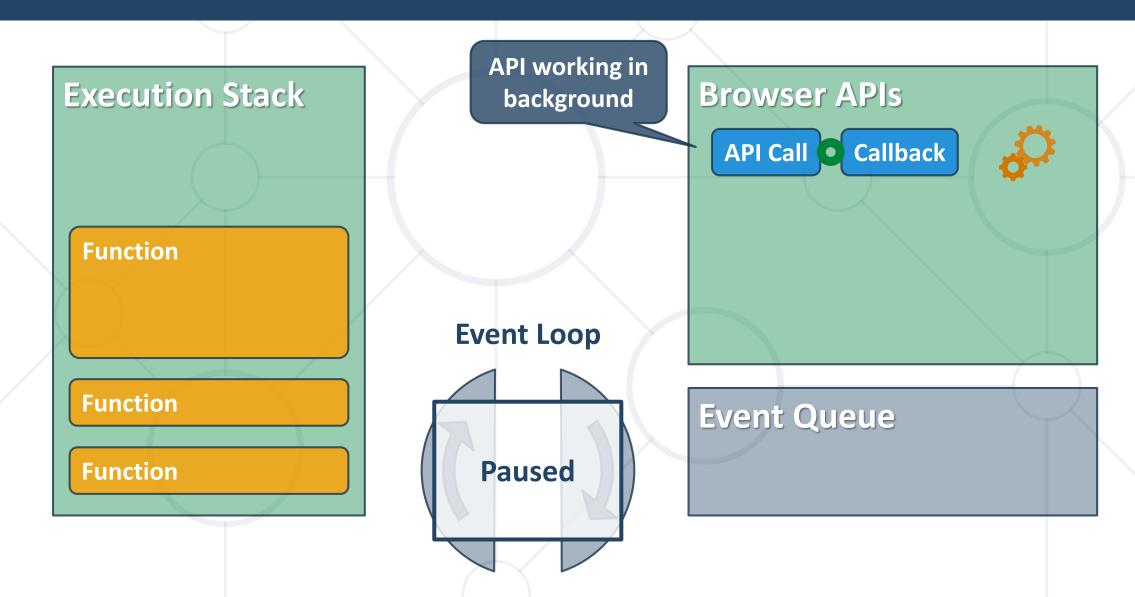

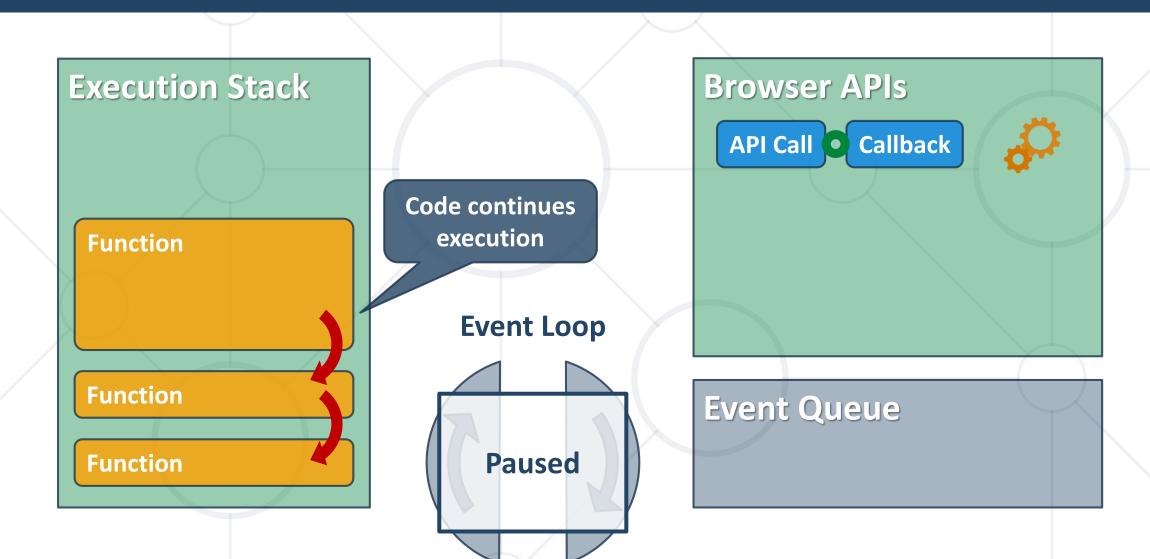

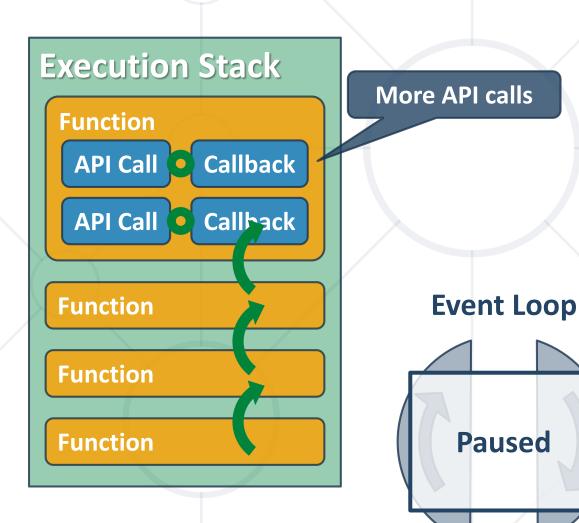

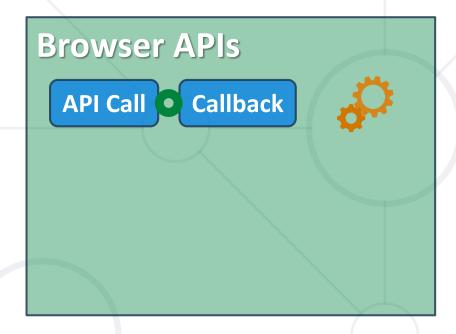

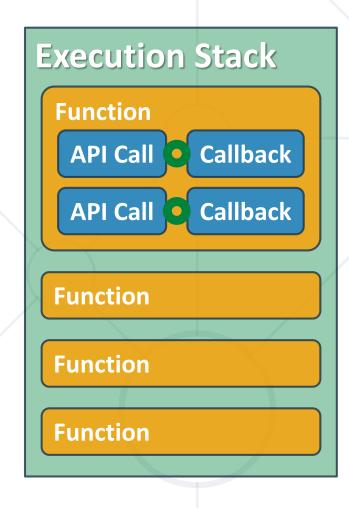

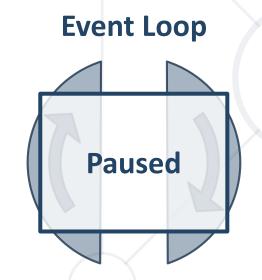

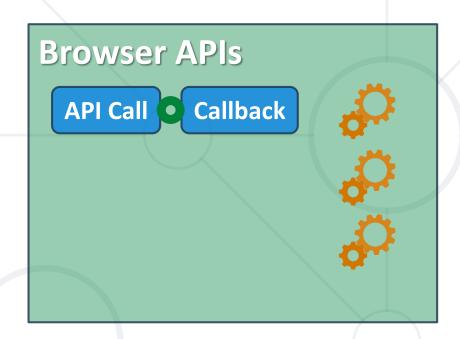

**Event Queue** 

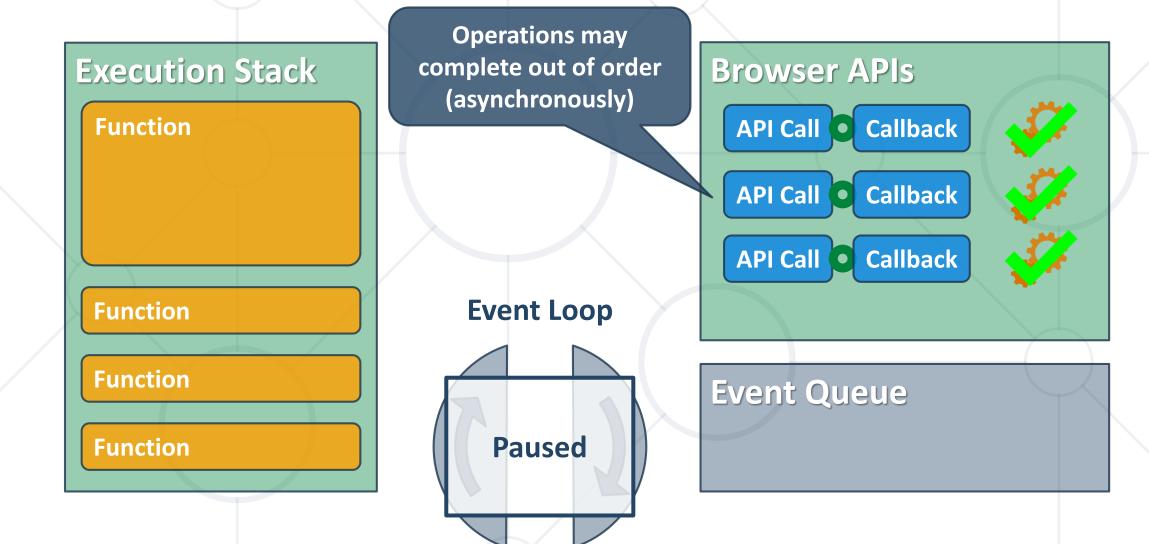

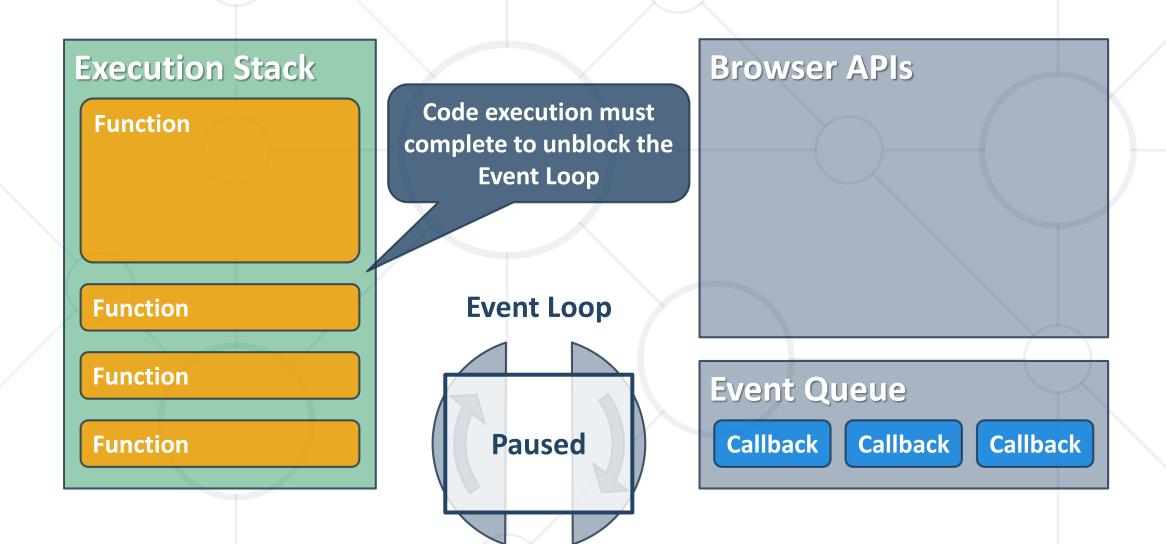

**Event Queue** 

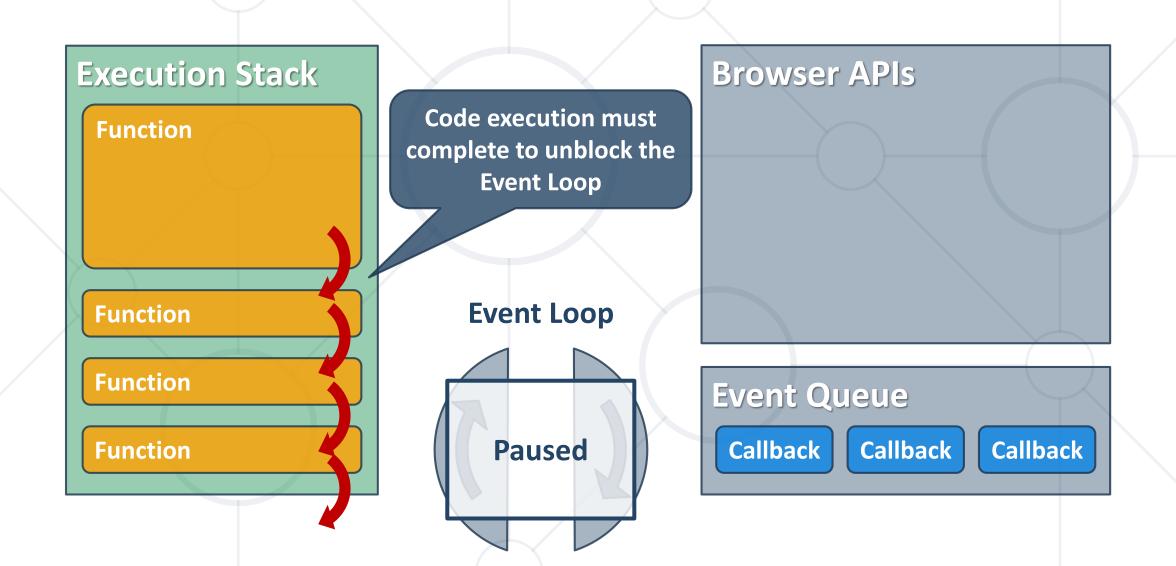

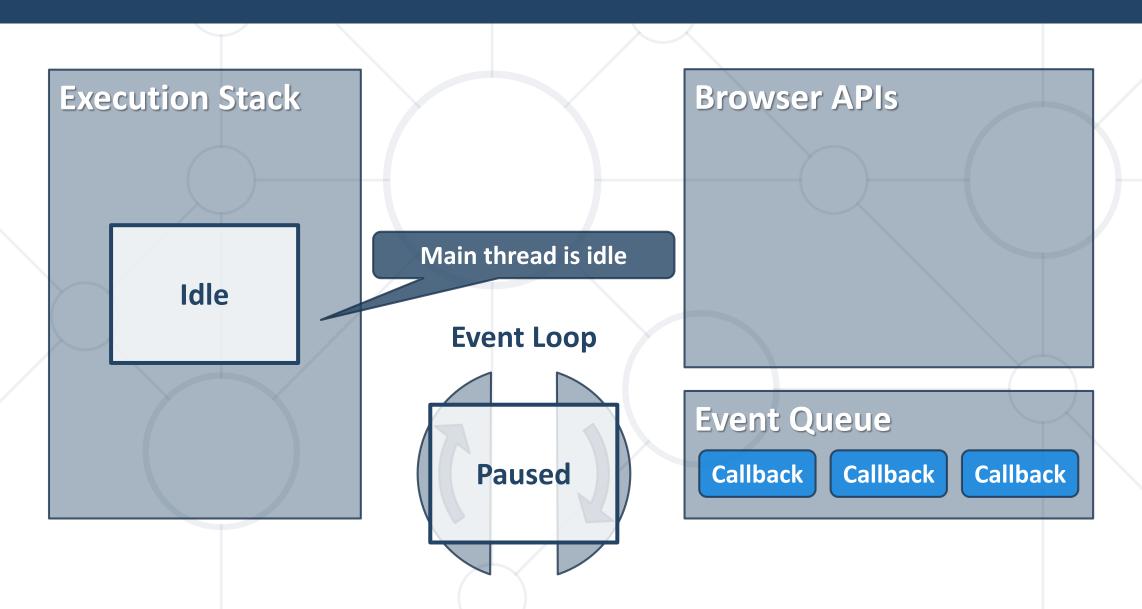

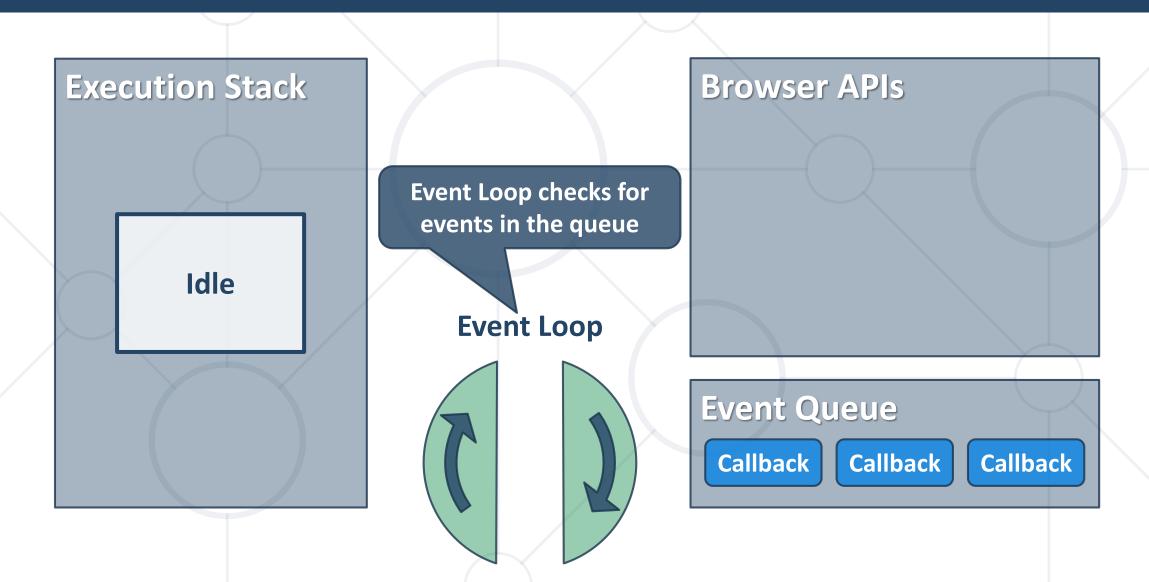

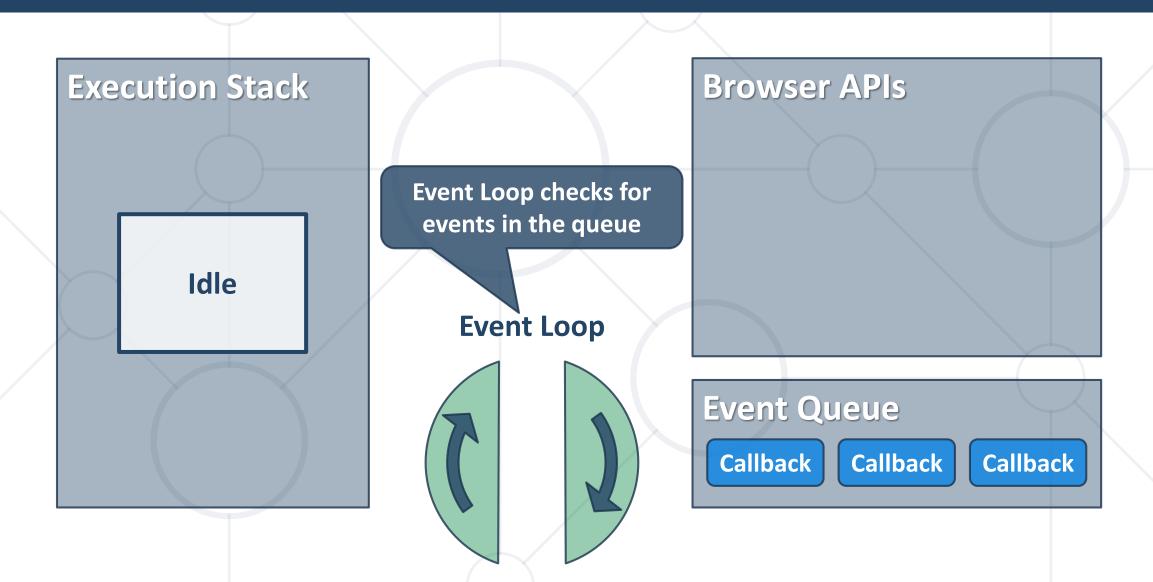

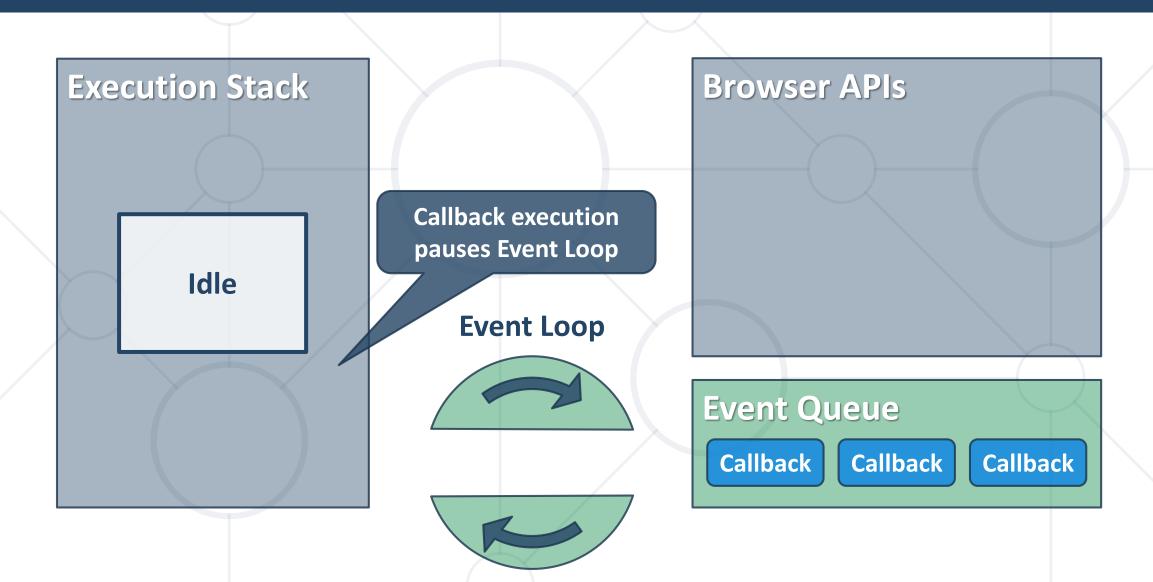

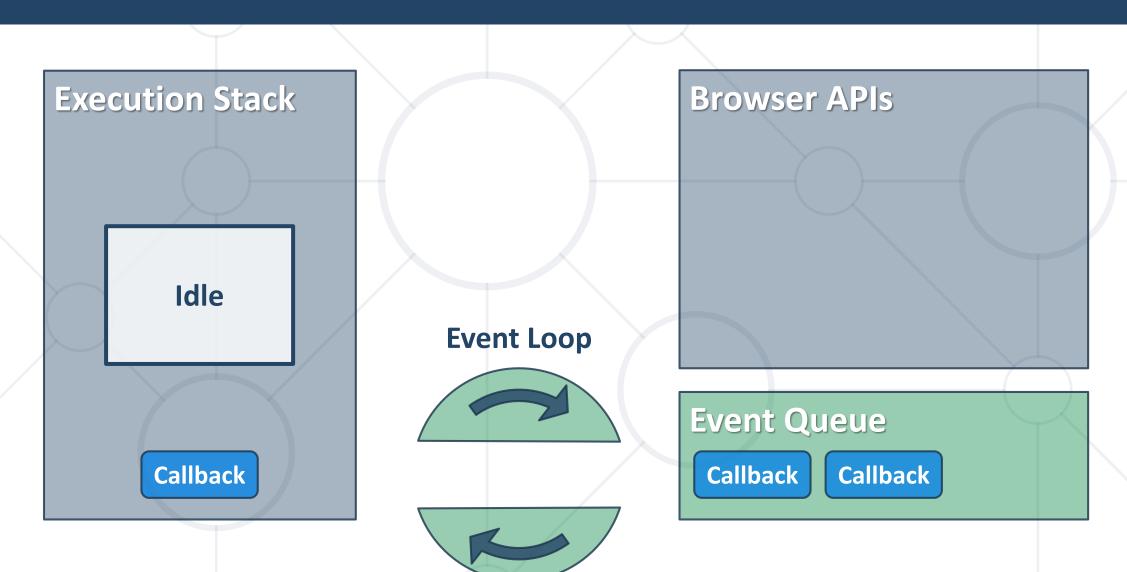

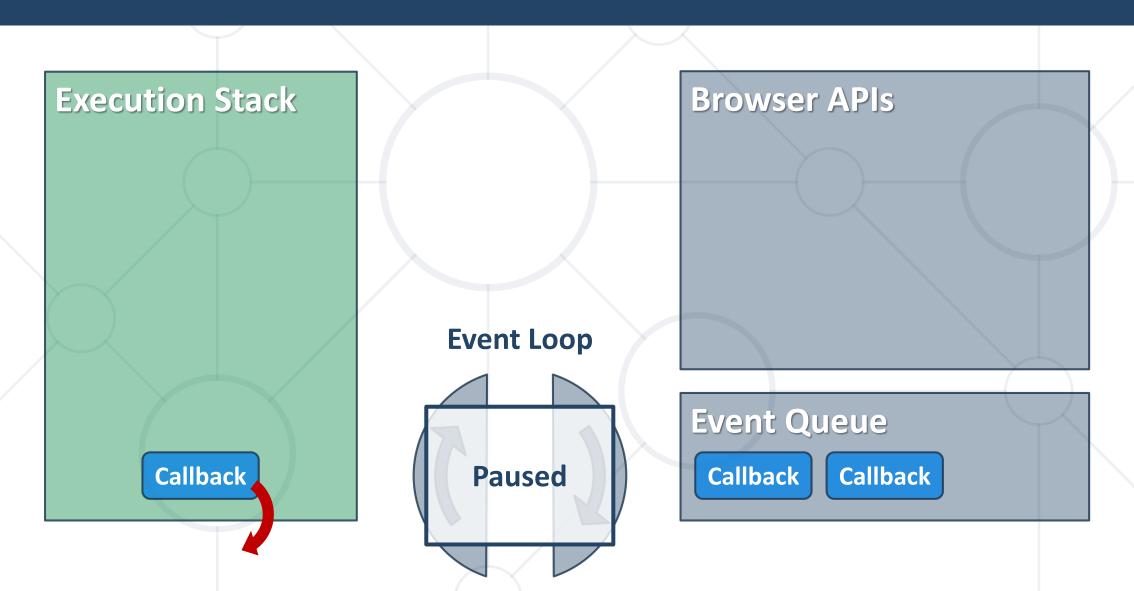

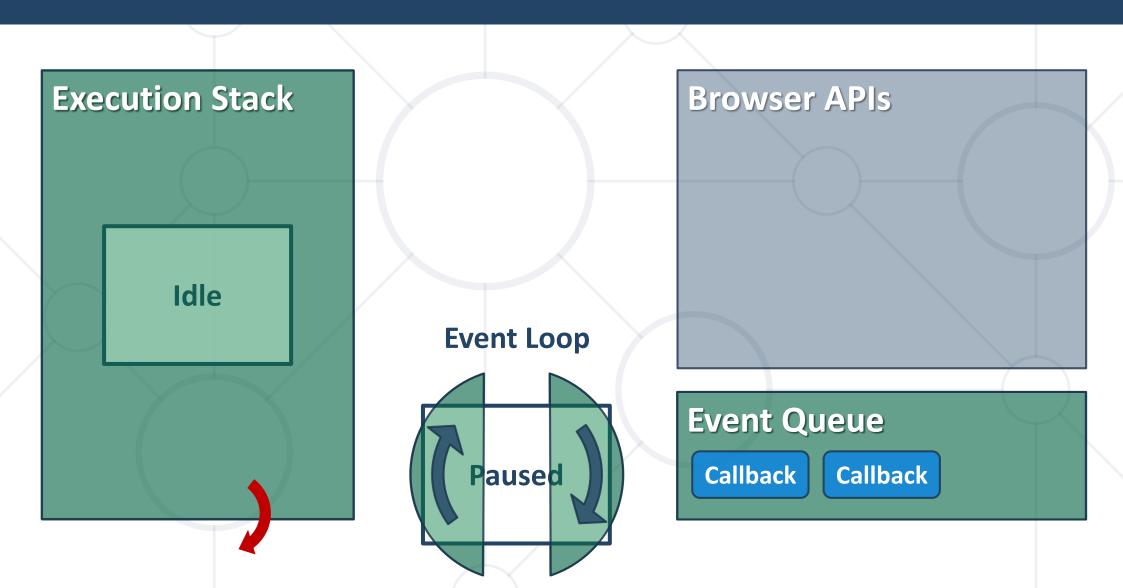

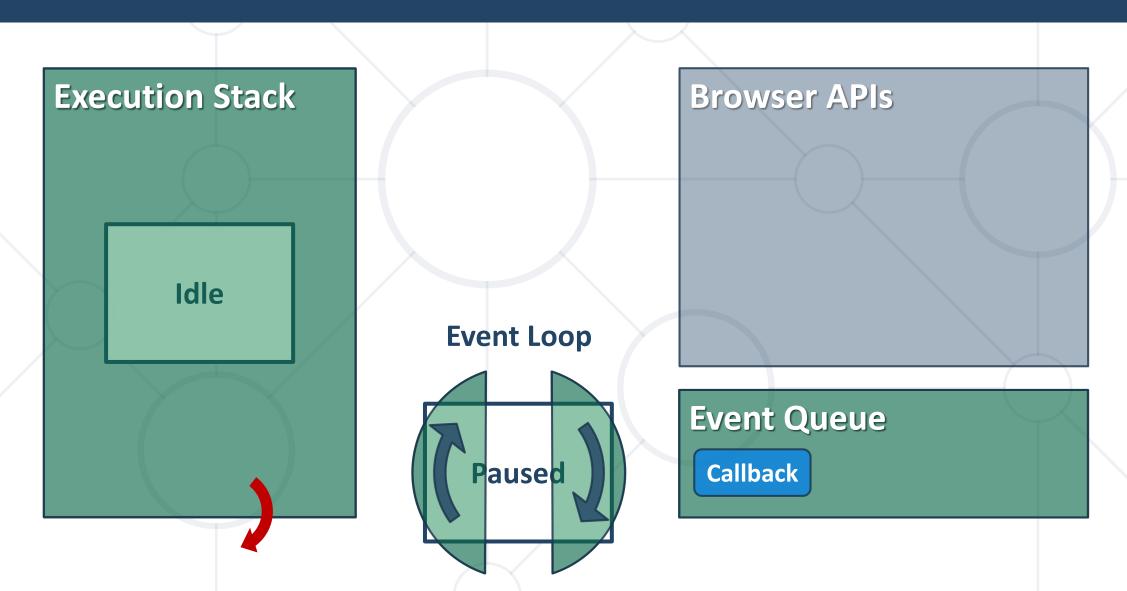

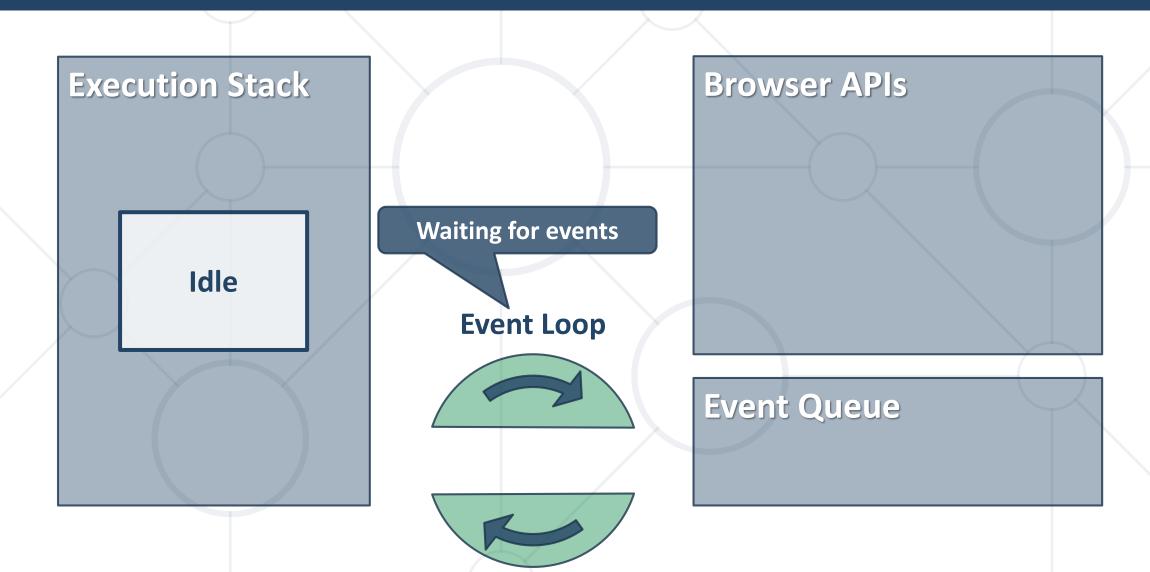

## **Promises**

**Objects Holding Asynchronous Operations** 

#### What is a Promise?

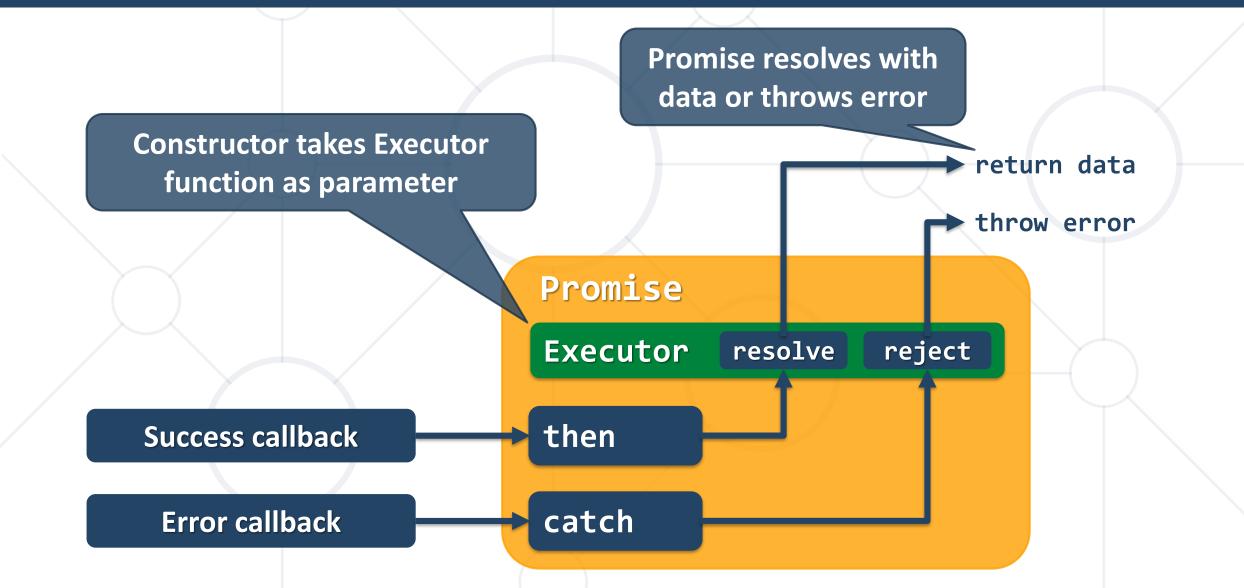

- A promise is an asynchronous action that may complete at some point and produce a value
- States:
  - Pending operation still running (unfinished)
  - Fulfilled operation finished (the result is available)
  - Failed operation failed (an error is present)
- Promises use the Promise class

new Promise(executor);

#### **Promise Flowchart**

# Promise.then() – Example

```
console.log('Before promise');
```

```
new Promise(function(resolve, reject) {
  setTimeout(function() {
    resolve('done');
  }, 500);_
            Resolved after 500 ms
.then(function(res) {
  console.log('Then returned: ' + res);
});
```

```
// Before promise

// After promise

// Then returned: done
```

```
console.log('After promise');
```

#### Promise.catch() – Example

```
console.log('Before promise');
```

```
new Promise(function (resolve, reject) {
    setTimeout(function () {
        reject('fail');
    }, 500);
    Rejected after 500 ms

    .then (function (result) { console.log(result); })
    .catch (function(error) { console.log(error); });
```

```
console.log('After promise');
```

#### **Promise Methods**

- Promise.reject(reason)
  - Returns an object that is rejected with the given reason
- Promise.resolve(value)
  - Returns an object that is resolved with the given value
- Promise.all(iterable)
  - Returns a promise
    - Fulfills when all of the promises have fulfilled
    - Rejects as soon as one of them rejects

# Promise Methods (2)

- Promise.allSettled(iterable)
  - Wait until all promises have settled
- Promise.race(iterable)
  - Returns a promise that fulfills or rejects as soon as one of the promises in an iterable is settled
- Promise.prototype.finally()
  - The handler is called when the promise is settled

#### What is Fetch?

- Uses Promises
- Enables a simpler and cleaner API
- Makes code more readable and maintainable

```
fetch('./api/some.json')
  .then(function(response) {...})
  .catch(function(err) {...})
```

# **Basic Fetch Request**

- The response of a fetch() request is a Stream object
- The reading of the stream happens asynchronously
- When the json() method is called, a Promise is returned
  - The response status is checked (should be 200) before parsing the response as JSON

```
if (response.status !== 200) {
    // handLe error
}
response.json()
    .then(function(data) { console.log(data)})
```

#### **GET Request**

 Fetch API uses the GET method so that a direct call would be like this

```
fetch('https://api.github.com/users/testnakov/repos')
   .then((response) => response.json())
   .then((data) => console.log (data))
   .catch((error) => console.error(error))
```

#### **POST Request**

 To make a POST request, we can set the method and body parameters in the fetch() options

```
fetch('/url', {
    method: 'post',
    headers: { 'Content-type': 'application/json' },
    body: JSON.stringify(data),
})
```

# **Body Methods**

- clone() create a clone of the response
- json() resolves the promise with JSON
- redirect() create new promise but with different URL
- text() resolves the promise with string
- arrayBuffer() resolve body with ArrayBuffer
- blob() resolve body with Blob (file, image, etc.)
- formData() resolve body with FormData

#### **Response Types**

- basic normal, same origin response
- cors response was received from a valid cross-origin request
- error error network
- opaque Response for "no-cors" request to cross-origin resource
- opaqueredirect the fetch request was made with redirect: "manual"

#### **Chaining Promises**

When working with a JSON API, you can:

The functions return promises which can be chained

```
fetch('users.json')
   .then(status)
   .then(json)
   .then(function(data) {...})
   .catch(function(error) {...});
```

#### **Problem: Load GitHub Commits**

```
GitHub username:
<input type="text" id="username" value="nakov" /> <br>
Repo: <input type="text" id="repo" value="nakov.io.cin" />
<button onclick="loadCommits()">Load Commits</button>
GitHub username:
<script>
                                      Repo: nakov.io.cin
                                                            Load Commits
  function loadCommits() {
     // Use Fetch API

    Svetlin Nakov: Delete Console.Cin.v11.suo

    Svetlin Nakov: Create LICENSE

    Svetlin Nakov: Update README.md

    Svetlin Nakov: Added better documentation

</script>
```

Simplified Promises

# **Async Functions**

- Returns a promise, that can await other promises in a way that looks synchronous
- Operate asynchronously via the event loop
- Contains an await expression that:
  - Is only valid inside async functions
  - Pauses the execution of that function
  - Waits for the Promise's resolution

# **Async Functions (2)**

```
function resolveAfter2Seconds() {
  return new Promise(resolve => {
    setTimeout(() => {
      resolve('resolved');
    }, 2000);
  });
}
```

```
Expected output:
// calling
// resolved
```

```
async function asyncCall() {
  console.log('calling');
  let result = await resolveAfter2Seconds();
  console.log(result);
}
```

# Async Functions (3)

- Do not confuse await with Promise.then()
  - await is always used for a single promise
  - To await two or more promises in parallel, use Promise.all()
- If a promise resolves normally, then await promise returns the result
- In case of a rejection, it throws an error

# Async/Await vs Promise.then

Promise.then

```
function logFetch(url) {
  return fetch(url)
    .then(response => {
      return response.text()
    .then(text => {
      console.log(text);
    .catch(err => {
      console.error(err);
    });
```

Async/Await

```
async function logFetch(url) {
 try {
    const response =
       await fetch(url);
    console.log(
      await response.text()
  catch (err) {
    console.log(err);
```

#### **Error Handling**

```
async function f() {
  try {
    let response = await fetch();
    let user = await response.json();
  } catch (err) {
    // catches errors both in fetch andresponse.json
    alert(err);
  }}
```

```
async function f() {
  let response = await fetch();
}
// f() becomes a rejected promise
f().catch(alert);
```

#### **Sequential Execution**

To execute different promise methods one by one, use Async /Await

```
function execute(x,sec) {
  return new Promise(resolve => {
  console.log('Start: ' + x);
    setTimeout(() => {
     console.log('End: ' + x);
     resolve(x);
  }, sec *1000); }); }
```

```
async function serialFlow() {
  let result1 = await execute(1, 1);
  let result2 = await execute(2, 2);
  let result3 = await execute(3, 3);
  let finalResult = result1 + result2 + result3;
  console.log(finalResult);
}
```

```
// Start: 1
// End: 1
// Start: 2
// End: 2
// Start: 3
// End: 3
// 6
```

#### **Concurrent Execution**

```
async function parallelFlow() {
  let result1 = execute(1,1);
  let result2 = execute(2,2);
  let result3 = execute(3,3);
  let finalResult = await result1 +
                    await result2 +
                    await result3;
  console.log(finalResult);
```

```
// Expected output:
// Start: 1
// Start: 2
// Start: 3
// End: 1
// End: 2
// End: 3
// 6
```

#### Summary

- Asynchronous programming
  - Runs several tasks in parallel, at the same time
- Promises hold operations
  - Can be resolved or rejected
- Async functions contain an await expression
  - Yields the execution
  - Waits for the Promise's resolution
